

CS151 Complexity Theory

Lecture 10
April 29, 2004

Outline

- Decoding Reed-Muller codes
- Transforming worst-case hardness into average-case hardness
- Extractors

April 29, 2004

CS151 Lecture 10

2

Decoding RM

- Main idea: reduce to decoding RS
RM codeword $p(x_1, x_2, \dots, x_t)$
of total degree at most h :

$$\begin{aligned} L_1(z) &= a_1z + b_1(1-z) \\ L_2(z) &= a_2z + b_2(1-z) \\ &\dots \\ L_t(z) &= a_tz + b_t(1-z) \end{aligned}$$

$$p|_L(z) = p(L_1(z), L_2(z), \dots, L_t(z))$$

"restriction to line $L(z)$ passing through a, b "

April 29, 2004

CS151 Lecture 10

3

Decoding RM

Two key observations:

1. If p has total degree at most h , then $p|_L$ has degree at most h
2. $p|_L$ is a univariate polynomial

April 29, 2004

CS151 Lecture 10

4

Decoding RM

- Example:

$$- p(x_1, x_2) = x_1^2x_2 + x_2^2$$

$$a = (2,1)$$

$$b = (1,0)$$

$$- L_1(z) = 2z + 1(1-z) = z + 1$$

$$- L_2(z) = 1z + 0(1-z) = z$$

$$- p|_L(z) = (z+1)^2z + z^2 = 2z^3 + 2z^2 + z$$

April 29, 2004

CS151 Lecture 10

5

Decoding RM

Key property:

- If pick a, b randomly in $(\mathbb{F}_q)^t$ then points in the vector

$$(az + b(1-z)) \quad z \in \mathbb{F}_q$$

are pairwise independent.

April 29, 2004

CS151 Lecture 10

6

Decoding RM

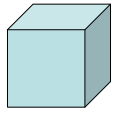

- Meaning of pairwise independent in this context:
- $L = az + b(1-z)$
for all $w, z \in \mathbf{F}_q$, $\alpha, \beta \in (\mathbf{F}_q)^t$
 $\Pr_{a,b}[L(w) = \alpha \mid L(z) = \beta] = 1/q^t$
- every pair of points on L behaves just as if it was picked independently

April 29, 2004

CS151 Lecture 10

7

Decoding RM (small error)

- The setup:
 - Codeword is a polynomial $p: (\mathbf{F}_q)^t \rightarrow \mathbf{F}_q$ with total degree h
 - $k = (h + t \text{ choose } t)$
 - $n = q^t$
- 
- Given received word $R: (\mathbf{F}_q)^t \rightarrow \mathbf{F}_q$
 - Suppose $\Pr_a[p(a) = R(a)] > 1 - \delta$
 - Try to recover p by accessing R

April 29, 2004

CS151 Lecture 10

8

Decoding RM (small error)

- To decode one position $a \in (\mathbf{F}_q)^t$:
 - pick b randomly in $(\mathbf{F}_q)^t$
 - L is line passing through a, b
 - q pairs $(z, R_L(z))$ for $z \in \mathbf{F}_q$
 - each point $L(z)$ random in $(\mathbf{F}_q)^t$
 - $E[\# \text{ errors hit}] < \delta q$
 - $\Pr_b[\# \text{ errors hit} > 4\delta q] < 1/4$ (Markov)
 - try to find degree h univariate poly. r for which
 $\Pr_z[r(z) \neq R_L(z)] \leq 4\delta$
- 

April 29, 2004

CS151 Lecture 10

9

Decoding RM (small error)

- with probability $3/4$ data is close to the univariate polynomial p_L , and then
 $r(1) = p_L(1) = p(a)$
- output $r(1)$
- repeat $O(\log n)$ times, choose top vote-getter
- reduces error probability to $1/3n$
- union bound: all n positions decoded correctly with probability at least $2/3$

April 29, 2004

CS151 Lecture 10

10

Decoding RM (small error)

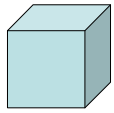

- Assume relative distance $1-h/q > 1/2$
- Previous algorithm works when $4\delta < 1/4$
- requires very small relative error $\delta < 1/16$

April 29, 2004

CS151 Lecture 10

11

List-decoding RM (large error)

- The setup:
 - Given received word $R: (\mathbf{F}_q)^t \rightarrow \mathbf{F}_q$
 - each nearby codeword is a polynomial $p: (\mathbf{F}_q)^t \rightarrow \mathbf{F}_q$ with total degree h .
 - $k = (h + t \text{ choose } t)$
 - $n = q^t$
- 
- By accessing R , try to recover all p such that
 $\Pr_a[p(a) = R(a)] > \epsilon$

April 29, 2004

CS151 Lecture 10

12

List-decoding RM (large error)

- Procedure (sketch):
 - pick a and b randomly in $(\mathbb{F}_q)^t$
 - L is line passing through a, b
 - q pairs $(z, R_{\perp L}(z))$ for $z \in \mathbb{F}_q$
 - each point $L(z)$ random in $(\mathbb{F}_q)^t$
 - $E[\# \text{ non-errors hit}] > \epsilon q$
 - $\Pr_{a,b}[\# \text{ non-errors hit} < \epsilon q/2] < 4/(\epsilon q)$ (Chebyshev)

April 29, 2004

CS151 Lecture 10

13

List-decoding RM (large error)

- using RS list-decoding, find list of all degree h univariate polynomials r_1, r_2, \dots, r_m for which

$$\Pr_z[r_i(z) = R_{\perp L}(z)] \geq \epsilon q/2$$
- One r_i is $p_{\perp L}$ (i.e., $r_i(z) = p_{\perp L}(z)$ for all z)
- How can we find that one?
- given $p(b)$, can find it with high probability:

$$\Pr_{a,b}[\text{exists } i \neq j \text{ for which } r_i(0) = r_j(0)] < 8m^2h/q$$
- find the *unique* r_i for which $r_i(0) = p(b)$; output $r_i(1)$, which should be $p_{\perp L}(1) = p(a)$

April 29, 2004

CS151 Lecture 10

14

List-decoding RM (large error)

- $\Pr_{a,b}[\# \text{ non-errors hit} < \epsilon q/2] < 4/(\epsilon q)$
- given $p(b)$, $\Pr_{a,b}[\text{fail to output } p(a)] < 8m^2h/q$
- $\Pr_{a,b}[\text{output } p(a)] > 1 - 4/(\epsilon q) - 8m^2h/q$
- Key: try for $O(\log n)$ random b values
 - for each b , try all q values for $p(b)$ (one is right!)
 - apply RM decoding from small error
 - each good trial gives small error required for previous decoding algorithm

April 29, 2004

CS151 Lecture 10

15

Decoding RM (large error)

- Requirements on parameters:
 - $\epsilon q/2 > (2hq)^{1/2} \Rightarrow q > 8h/\epsilon^2$ (for RS list decoding)
 - $4/(\epsilon q) < 1/64 \Rightarrow q > 256/\epsilon$
 - know $m < 2/\epsilon$ from q -ary Johnson bound
 - $8m^2h/q < 32h/(q\epsilon^2) < 1/64 \Rightarrow q > 2^{11}h/\epsilon^2$
- conclude: $\Pr_{a,b}[\text{output } p(a)] > 1 - 1/32$

April 29, 2004

CS151 Lecture 10

16

Decoding RM (large error)

$$\Pr_{a,b}[\text{fail to output } p(a)] < 1/32$$

$$\Pr_b[\Pr_a[\text{fail to output } p(a)] > 1/16] < 1/2$$

- on trial with correct value for $p(b)$, with probability at least $1/2$ RM decoder from small error is correct on all a
- repetition decreases error exponentially
- union bound: all p with agreement ϵ included in list

April 29, 2004

CS151 Lecture 10

17

Local decodability

- Amazing property of decoding method:

R: 0 0 1 0 1 0 1 0 0 0 1 0 0

C(m): ? ? ? ? ? ? 1 ? ? ? ? ? ?

- Local decodability: each symbol of $C(m)$ decoded by looking at small number of symbols in R

April 29, 2004

CS151 Lecture 10

18

Local decodability

- Local decodability: each symbol of $C(m)$ decoded by looking at small number of symbols in R
 - small decoding circuit D
 - small circuit computing R
 - implies small circuit computing $C(m)$

April 29, 2004

CS151 Lecture 10

19

Concatenation

- Problem: symbols of F_q rather than bits
- Solution: encode each symbol with binary code
 - our choice:
 - RM with degree $h \leq 1$, field size 2
 - # variables $t = \log q$
 - also called “Hadamard code”
 - Schwartz-Zippel implies distance = $\frac{1}{2}$

April 29, 2004

CS151 Lecture 10

20

Concatenation

- decoding:
 - whenever would have accessed symbol i of received word, decode binary code first, then proceed

April 29, 2004

CS151 Lecture 10

21

The concatenated code

- outer code:** RM with parameters
 - field size q , degree h , dimension t
 - # coefficients $(h+t \text{ choose } t) > k$
 - $q^t = \text{poly}(k)$
- inner code:** RM with parameters
 - field size $q' = 2$
 - degree $h' = 1$
 - dimension $t' = \log q$
- block length** $n = q^t q = \text{poly}(k)$

April 29, 2004

CS151 Lecture 10

22

Codes and Hardness

- Recall our strategy:
 - truth table of $f: \{0,1\}^{\log k} \rightarrow \{0,1\}$
(worst-case hard)
 $m: 01100010$
 - truth table of $f': \{0,1\}^{\log n} \rightarrow \{0,1\}$
(average-case hard)
 - $C(m): 01100010001000010$

April 29, 2004

CS151 Lecture 10

23

Hardness amplification

- Claim:** $f \in E \Rightarrow f' \in E$
- $f \in E \Rightarrow f$ computable by a TM running in time $2^{c(\log k)} = k^c$
 - to write out truth table of f : time kk^c
 - to compute truth table of f' : time $\text{poly}(n, k)$
 - recall $n = \text{poly}(k)$
 - f' computable by TM running in time $n^c = 2^{c(\log n)} \Rightarrow f' \in E$

April 29, 2004

CS151 Lecture 10

24

Hardness amplification

- Need to prove: if f is s' -approximable by circuit C , then f is computable by a size $s = \text{poly}(s')$ circuit.

April 29, 2004

CS151 Lecture 10

25

Hardness amplification

- suppose f is s' -approximable by C
 - $\Pr_x[C(x) = f'(x)] \geq \frac{1}{2} + 1/s'$
 - at least $s'/2$ "inner" blocks have C, f' agreement $\frac{1}{2} + 1/(2s')$
 - Johnson Bound: at most $O(s'^2)$ inner codewords with this agreement
 - find by brute force search: time = $O(q)$
 - pick random msg. from list for each symbol
 - get "outer" received word with agreement $1/s'^3$

April 29, 2004

CS151 Lecture 10

26

Hardness amplification

- "outer" received word with agreement $\epsilon = 1/s'^3$
- can only uniquely decode from agreement $> \frac{1}{2}$ (since relative distance < 1)
- our agreement $\ll \frac{1}{2}$

need to use list-decoding of RM for large error

April 29, 2004

CS151 Lecture 10

27

Setting parameters

- have to handle agreement $\epsilon = 1/s'^3$
- pick q, h, t :
 - need $q > \Omega(h/\epsilon^2)$ for decoder to work
 - need $(h + t \text{ choose } t) > k$ (note $s' < k$)
 - need $q^t = \text{poly}(k)$
- $h = s'$
- $t \approx (\log k)/(\log s')$
- $q = \Omega(h/\epsilon^2) = \Omega(s'^3)$

April 29, 2004

CS151 Lecture 10

28

List-decoding RM

- final result: short list of circuits
- size = $\text{poly}(q)\text{poly}(s') = \text{poly}(s')$
- one computes f exactly!
- circuit for f of size $\text{poly}(s')$

April 29, 2004

CS151 Lecture 10

29

Putting it all together

Theorem 1 (IW, STV): If \mathbf{E} contains functions that require size $2^{\Omega(n)}$ circuits, then \mathbf{E} contains $2^{\Omega(n)}$ -unapproximable functions.

- Theorem (NW): if \mathbf{E} contains $2^{\Omega(n)}$ -unapproximable functions then $\mathbf{BPP} = \mathbf{P}$.

Theorem 2 (IW): \mathbf{E} requires exponential size circuits $\Rightarrow \mathbf{BPP} = \mathbf{P}$.

April 29, 2004

CS151 Lecture 10

30

Putting it all together

- Proof of Theorem 1:
 - let $f = \{f_n\}$ be such a function that requires size $s = 2^{\delta n}$ circuits
 - define $f' = \{f'_n\}$ be just-described encoding of (truth table of) f
 - just showed: if f' is $s' = 2^{\delta' n}$ -approximable, then f is computable by size $s = \text{poly}(s') = 2^{\delta n}$ circuit.
 - contradiction.

April 29, 2004

CS151 Lecture 10

31

Extractors

- PRGs: can remove randomness from algorithms
 - based on unproven assumption
 - polynomial slow-down
 - not applicable in other settings
- Question: can we use “real” randomness?
 - physical source
 - imperfect – biased, correlated

April 29, 2004

CS151 Lecture 10

32

Extractors

- “Hardware” side
 - what physical source?
 - ask the physicists...
- “Software” side
 - what is the minimum we need from the physical source?

April 29, 2004

CS151 Lecture 10

33

Extractors

- imperfect sources:
 - “stuck bits”: 
 - “correlation”: 
 - “more insidious correlation”: 
- there are specific ways to get independent unbiased random bits from specific imperfect physical sources

April 29, 2004

CS151 Lecture 10

34

Extractors

- want to assume we don't know details of physical source
- **general model** capturing all of these?
 - yes: “min-entropy”
- **universal procedure** for all imperfect sources?
 - yes: “extractors”

April 29, 2004

CS151 Lecture 10
