# Outline

### 2 Unit-Demand

- 3 Multi-Unit-Demand
- 4 Capped Additive

# Outline

∃ →

▲ 周 → - ▲ 三

A combinatorial public project is a game in which the goal is to choose k items from a set to provide for shared use among n agents.

< A > < > > <

A combinatorial public project is a game in which the goal is to choose k items from a set to provide for shared use among n agents.

#### Example

Suppose you are the administrator for a small park. You have room for 3 pieces of equipment. Which pieces do you choose in order to make local families happiest?

# Park Design

## So many choices for equipment

# Park Design

#### So many choices for equipment

And every parent has an opinion

- "There must be a swing set"
- "If there isn't tetherball, the terrorists have already won"
- "My kids need a merry go round and a playground equipment"
- "I'll picket if there's anything dangerous"
- "Kids need exercise. No equipment that can be used while sitting!"

You can't make everyone happy, but you can try to make the park as good for the public as possible.

### Definition (Social Welfare)

Suppose that each agent *i* gets value  $v_i(S)$  for allocation *S*. Then the social welfare of *S* is

# $\sum_{i} v_i(S)$

## More than computation

So now we have a computational problem. Given the valuations  $v_1, \ldots, v_n$  of the *n* agents, find a set *S* of size *k* maximizing the social welfare. Unfortunately, we have the added difficulty that people will lie.

## More than computation

So now we have a computational problem. Given the valuations  $v_1, \ldots, v_n$  of the *n* agents, find a set *S* of size *k* maximizing the social welfare. Unfortunately, we have the added difficulty that people will lie.

### Example (Elections)

In the US, people will lie on ballots that they desire one of the major party candidates, rather than "throw their votes away" on preferred third party candidates.

## Truthfulness

We would like to design a mechanism whereby we are able to elicit the true valuations and approximate the social welfare well.

→ < ∃ >

## Truthfulness

We would like to design a mechanism whereby we are able to elicit the true valuations and approximate the social welfare well.

In order to do so, we allow money to change hands. We already know how to achieve truthful prices via the VCG mechanism. This allows for any allocation algorithm to be made truthful iff it is maximal in range.

## Truthfulness

We would like to design a mechanism whereby we are able to elicit the true valuations and approximate the social welfare well.

In order to do so, we allow money to change hands. We already know how to achieve truthful prices via the VCG mechanism. This allows for any allocation algorithm to be made truthful iff it is maximal in range.

#### Definition (Maximal in Range)

An allocation algorithm is maximal in range if there exists a set R such that it always outputs a member of R maximizing the social welfare.

VCG-based mechanisms are the only known general method for achieving truthfulness in games like this. Furthermore, they are sometimes the only way to get truthfulness.

Theorem (Roberts, 1979)

The only truthful mechanism for general games is the VCG mechanism.

Papadimitriou, Schapira and Singer showed this for public projects in 2008

# Performance of MIR mechanisms

#### Theorem

A maximal in range allocation algorithm for any NP-hard combinatorial public project cannot approximate the welfare with a ratio better than  $\sqrt{m}$  unless NP  $\subseteq$  P/poly.

### Proof (Sketch).

• A mechanism that gets better than a  $\sqrt{m}$  ratio requires an exponential range for sufficiently expressive valuation classes (PSS 08)

# Performance of MIR mechanisms

#### Theorem

A maximal in range allocation algorithm for any NP-hard combinatorial public project cannot approximate the welfare with a ratio better than  $\sqrt{m}$  unless NP  $\subseteq$  P/poly.

### Proof (Sketch).

- A mechanism that gets better than a √m ratio requires an exponential range for sufficiently expressive valuation classes (PSS 08)
- By Sauer's lemma, an exponential range must contain a polynomial-sized subset S\* of items allocated in every way

# Performance of MIR mechanisms

#### Theorem

A maximal in range allocation algorithm for any NP-hard combinatorial public project cannot approximate the welfare with a ratio better than  $\sqrt{m}$  unless NP  $\subseteq$  P/poly.

### Proof (Sketch).

- A mechanism that gets better than a √m ratio requires an exponential range for sufficiently expressive valuation classes (PSS 08)
- By Sauer's lemma, an exponential range must contain a polynomial-sized subset S\* of items allocated in every way
- We construct instances in which it is NP-hard to determine which members of *S*<sup>\*</sup> should be selected. These follow fairly directly from the proofs of NP-hardness.

The proof framework described requires different proofs depending on what class of valuations the agents are allowed to have.

- ∢ ∃ ▶

# **Computing Values**

Computing  $v_i(S)$  for an agent may seem difficult, but it can be accomplished easily via matching:

3

(人間) トイヨト イヨト

This can be extended to a solution for 2 agents via network flow.

This can be extended to a solution for 2 agents via network flow.

#### Theorem

The public projects problem with 2 multi-unit-demand agents is in P.

This can be extended to a solution for 2 agents via network flow.

#### Theorem

The public projects problem with 2 multi-unit-demand agents is in P.

Each choice of k items corresponds to a flow.

Dave Buchfuhrer (Caltech)

This can be extended to a solution for 2 agents via network flow.

#### Theorem

The public projects problem with 2 multi-unit-demand agents is in P.

Each choice of k items corresponds to a flow.

Dave Buchfuhrer (Caltech)

#### Theorem

The public projects problem with 3 multi-unit-demand agents is NP-hard.

We use a reduction from 3-dimensional matching.

#### Theorem

The public projects problem with 3 multi-unit-demand agents is NP-hard.

We use a reduction from 3-dimensional matching.

Definition (3-Dimensional Matching) Input: A set  $M \subseteq [q] \times [q] \times [q]$ . Decision Problem: Does there exist some  $M' \subseteq M$  such that |M'| = qand no two members of M' agree on any coordinate?

#### Theorem

The public projects problem with 3 multi-unit-demand agents is NP-hard.

We use a reduction from 3-dimensional matching.

## Definition (3-Dimensional Matching)

**Input:** A set  $M \subseteq [q] \times [q] \times [q]$ . **Decision Problem:** Does there exist some  $M' \subseteq M$  such that |M'| = q and no two members of M' agree on any coordinate?

#### Reduction

The *i*th agent has value equal to the number of distinct *i*th coordinates.

Each of the 3 agents has q unit-demand valuations. For each  $i, j, k \in M$ , create an item that is only valued by agent 1's *i*th valuation, agent 2's *j*th valuation and agent 3's *k*th valuation. Allow for q items to be chosen.

< ロト < 同ト < ヨト < ヨト

# 2/3 approximation

Although VCG can't beat a  $\sqrt{m}$  approximation for 3 agents, we can use a randomized VCG strategy to get an expected 2/3 approximation.

#### Theorem

The below mechanism is universally truthful and achieves at least a 2/3 approximation in expectation.

#### Mechanism

- Choose 2 of the 3 agents uniformly at random
- Solve exactly for these 2 agents using the VCG mechanism

# Summary

- Multi-unit-demand is easy for 2 agents, but hard for 3
- Despite the failure of the VCG mechanism for 3 agents, we can randomize for a constant approximation

# Outline

- **Capped Additive** 4

▲ 同 ▶ → 三 ▶

# Motivating Example

Now that the mall visitors are well-fed, they head to the gym. The gym has room for k pieces of exercise equipment.

- Visitors want to maximize gym hours
- Visitors have differing abilities on each machine
- Visitors have time constraints on their workouts

## Definition

## Definition (Capped Additive Valuation)

An agent with a capped additive valuation has private values  $w_j$  for each item j, and a value limit b, and has value

$$w_i(S) = \min\left(\sum_{j \in S} w_j, b\right)$$

for set S.

#### Theorem

The public projects problem with capped-additive agents is NP-hard.

We reduce from subset sum.

< 3 >

#### Theorem

The public projects problem with capped-additive agents is NP-hard.

We reduce from subset sum.

## Definition (Subset Sum)

**Input:** A set of positive integers  $w_1, \ldots, w_\ell$ , and a positive integer t**Decision Problem:** Does there exist a set  $S \subseteq [\ell]$  such that  $\sum_{i \in S} w_i = t$ ?

#### Theorem

The public projects problem with capped-additive agents is NP-hard.

We reduce from subset sum.

## Definition (Subset Sum)

**Input:** A set of positive integers  $w_1, \ldots, w_\ell$ , and a positive integer t**Decision Problem:** Does there exist a set  $S \subseteq [\ell]$  such that  $\sum_{i \in S} w_i = t$ ?

### Proof.

- Add  $\ell$  integers  $w_{\ell+1}, \ldots, w_{2\ell} = 0$ . There are  $m = 2\ell$  items and  $k = \ell$ .
- Agent 1 has value 2w<sub>j</sub> for item j and budget 2t

• Let  $W = \max_j w_j$ . Agent 2 has value  $W - w_j$  for item j and  $b = \infty$ 

• Social welfare  $\ell W + t$  is achievable iff  $\exists S, \sum_{i \in S} w_i = t$ 

# Pseudo-Poly Algorithm

We can use dynamic programming if the valuations are small.

#### Theorem

There is a pseudo-polynomial time algorithm for the public projects problem with a constant number of capped-additive agents.

### Algorithm (Dynamic Programming)

- Create an n+2 dimensional table
- Entry v<sub>1</sub>,..., v<sub>n</sub>, i, j denotes whether there exists a set S ⊆ [i], |S| = j such that agent ℓ has value v<sub>ℓ</sub>.
- The table has poly size if no agent can have superpolynomial value
- If we fill in all the entries for i 1, j and i 1, j 1, we can easily fill in all the entries for i, j

< ロ > < 同 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ >

## Wait a second...

#### Theorem

No truthful poly-time mechanism for public projects can achieve better than a  $\sqrt{m}$  approximation unless NP  $\subseteq$  P/poly.

#### Proof.

- Our results show hardness for VCG to do better than  $\sqrt{m}$
- For a single agent, any mechanism must be maximal-in-range to be truthful, so VCG is all there is

## Wait a second...

#### Theorem

No truthful poly-time mechanism for public projects can achieve better than a  $\sqrt{m}$  approximation unless NP  $\subseteq$  P/poly.

#### Proof.

- Our results show hardness for VCG to do better than  $\sqrt{m}$
- For a single agent, any mechanism must be maximal-in-range to be truthful, so VCG is all there is

As this is submodular, we can get a 1 - 1/e greedy approximation.

Both the agent and the mechanism want the social welfare maximized, but if we want truthfulness, they can't even do as well as the greedy algorithm.

一日、

# Summary

No truthful mechanism gets a good approximation despite the lack of conflicting goals.

▲ @ ▶ < ∃ ▶</p>

# Outline

### 6 Summary and Conclusions

- ∢ ≣ →

# Summary of Results

VCG can't get any constant approximation for

- *n* unit-demand agents
- 3 multi-unit-demand agents
- 2 capped additive agents
- 1 coverage agent

But

- There is a constant approximation for a special case of unit-demand
- A solution for 2 multi-unit-demand agents can be used to get a 2/3 approximation for 3
- There is an FPTAS for capped additive agents
- All truthful mechanisms are VCG-based for coverage valuation agents

# Conclusions and Open Problems

- For public projects, we have to look beyond the VCG mechanism Can we develop better truthful mechanisms than VCG?
- In some situations, truthfulness is inherently flawed What should we use when truthfulness doesn't fit?
